RF Exposure Analysis

This proposal specifies horizontal and vertical radiation of 3.6 kilowatts at 131 meters above ground level. Using the worst case model of 3.6 KW (H) + 3.6 KW(V) at 129 meters (toward the tower base with NO compensation for downward radiation), we calculate the absolute worst case power density to be 14.45 uW/cm^2 . The worst case calculated power density at a level of 2 meters above ground is less than 8% of the FCC's recommended maximum limit of $.2\text{mW/cm}^2$ for FM channels applicable to general population / uncontrolled exposure areas. The calculated power density is less than 2% of the recommended limit for occupational / controlled areas. Therefore it is believed that this proposal fully complies with all established limits for non-ionizing radiation / RF exposure currently in effect.
