

The transmit and receive antennas for FM translator W233BM are mounted on separate, identical, triangular, uniform cross section, self-supporting towers.

Each tower has 30' of steel on a short concrete base. There is no base insulator on either tower. The towers are approximately 40" face, and are approximately 12' apart.

This information is based both on a structural report and on my personal observation of the site. The information is true and accurate to the best of my knowledge and belief.
